Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
US 6092078	A	32	G06F-017/30	CIP of application US 9866071

Abstract (Basic): US 6092078 A

NOVELTY - An initiation message is transmitted from a data receiving node (3104) to a network enabling input-output device (NEIOD). The NEIOD in response to initiation message, transmits a preparation message to the data receiving node and data is transmitted to the data receiving node over open data channel.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for network enabling input-output device.

USE - For operating peripheral data gathering devices on a network for data communication.

ADVANTAGE - Allows more complete integration and lower cost of combined call and replay module and peripheral device. Connection is kept open and updated data can be transmitted without waiting for a request for updated data.

DESCRIPTION OF DRAWING(S) - The figure shows the schematic diagram of construction of web page.

Data receiving node (3104)

Abstract (Basic): EP 991240 A2

NOVELTY - The method involves a first client (12) sending an open connection request to the server (10) in an attempt to open a connection with the server. The server checks to determine if a **connection** with another client is currently **open**. The server accepts the connection request and stores predetermined client information in the event a connection with another client is not currently open. The client sends a datagram-based protocol request for a predetermined action to the server. The server determines if the predetermined action is a protected action and whether the request is from the client that has the currently open connection. The server **sends sending** an error **message** to any **client** not having a currently open connection which makes a datagram-based protocol request for a protected action. The server processes a datagram-based protocol request when made by the client having a currently open connection. One of the client and the server closing the open connection upon completion of an activity

DETAILED DESCRIPTION - . An INDEPENDENT CLAIM is included for (1) a method of preventing multiple client access via Simple Network Management Protocol

USE - For preventing multiple access of datagram based control protocols.

ADVANTAGE - Provides improved server which utilizes connectionless protocol for control data and connection oriented protocol for scan data.

DESCRIPTION OF DRAWING(S) - The figure shows an overview of the network system.

					CIP of application US 94340172
					CIP of patent US 5506954

Abstract (Basic): US 5600797 A

The system includes a management computer and one or more client computers interconnected over a computer network. The client computers can communicate over the computer network. The management computer allocates bandwidth to the client computers for communication sessions over the computer network. Each client computer that is participating in an **active communication session** periodically **transmits a message** over the **computer network** to inform the management computer of current status of the **active communication session**. If the management computer receives a message from a client computer about a communication session of which the management computer was not previously aware, then the management computer allocates bandwidth for the communication session.

ADVANTAGE - Provides efficient management of allocation of finite bandwidth available for conferences.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
US 5583993	A	18	G06F-015/16	

Abstract (Basic): US 5583993 A

The method involves activating a shared space session. A first shared space view is displayed on a screen of a first computer system when the shared space **session** is **active**. Whether an input has been made in the first shared space view of the first computer system is automatically determined when the first shared space view is displayed. The input in the first shared space view is implemented when it has been determined that the input has been made is the first shared space view. A shared space **message** is automatically **sent** to a remote **computer** system when the input has been implemented in the first shared space view. Whether a shared space message indicative of a remotely recognised input has been received from the remote computer system is automatically determined. The shared space message into the first shared space view is implemented when it has been determined that the shared space message has been received.

ADVANTAGE - Allows collaboration of ideas to occur in much same way as if participants were in same room and using same sheet of paper or blackboard.

ES 2054078	T3			H04L-012/24	Based on patent EP 367699
CA 1319758	C			G06F-015/16	

Abstract (Basic): EP 367699 A

The network is partitioned into Non-Focal Point (NFP) nodes and at least one Focal Point (FP) node assigned to provide management services to a selected group of NFP nodes and which has a sphere of control table (SOC) that includes a list of the NFP nodes it is servicing. Each NFP node has an authorisation table that identifies the FP node that services it.

A "Request to be Your Focal Point" **message** is **generated** at an FP **node** and sent to active NFP nodes. NFP nodes respond only after ascertaining that the FP node is their primary focal point node for the service concerned, thereafter generating and forwarding information e.g. error messages to the FP node.

ADVANTAGE - Flexible. Overlapping control possible. Secondary and backup status can be included. (19pp Dwg.No.1/11

ABSTRACT

PROBLEM TO BE SOLVED: To give the message that a processing request destination computer is in an idle state to a request source computer in an early stage when the computer capable of being transited to the idle state is used.

SOLUTION: The processors 102 of the respective computers 101 are constituted so as to be capable of being transited to the idle state. When the computer provided with the processor in the idle state receives a certain message from another computer, the message that the processor is in the idle state is generated and transmitted to the request source. When the message is a processing request, the processor is started and shifted to a stand-by state. As soon as the message is received, the request source transmits the processing request again so that the request destination computer receiving the request is already in the stand-by state and the request is immediately processed

ABSTRACT

PURPOSE: To conduct a self-diagnosis of whether the device is normal or not with constitution which is inexpensive in economy and simple by providing

an operation holding circuit which holds a 1st state in response to a 1st level signal and is inverted from the 1st state to a 2nd state in response to a 2nd level signal.

CONSTITUTION: A low-level signal L is outputted as the 1st level signal to a 1st terminal PA. At this time, a 2nd terminal PB is in a high impedance state, and consequently the 2nd terminal PB is in a low-level state. In this state, a high-level signal is outputted as the 2nd level signal to the 2nd terminal PB. Once the high-level signal is supplied to the 2nd terminal PB, a 2nd transistor(TR) Q(sub 2) turns ON and then a 1st TR Q(sub 1) also turns ON. When both the TRs Q(sub 1) and Q(sub 2) turn on, a source voltage V(sub ss) is supplied to the 1st terminal PA through the 1st TR Q(sub 1) and a resistance R(sub 1), and consequently the 1st terminal PA changes into the high-level state.

JAPIO CLASS: 45.2 (INFORMATION PROCESSING -- Memory Units); 45.1 (INFORMATION PROCESSING -- Arithmetic Sequence Units)

ABSTRACT

PURPOSE: To omit the intervention of an operator in a state monitoring mode in order to improve the reliability and also to reduce the load needed for a state monitoring operation.

CONSTITUTION: A virtual host computer 3a receives the messages from other computers 3a to 3d at each fixed interval and writes the data on these message transmitter computers into a state monitor map. Then the computer 3a returns the answer messages to the transmitter computers to show the normal reception of those received messages. Thus the computer 3a monitors the states of the computers 3b to 3d based on the state monitor map and also sends this map to each of these computers as an answer message. If the virtual computer 3a has a fault, one of computers 3b to 3d carries on the state monitoring operation in place of the faulty computer 3a. Furthermore the present time information on the computer 3a is added to an answer message and transmitted.

ABSTRACT

PURPOSE: To monitor the state of the system at an electronic mail terminal
by using electronic mail suitable for monitoring the state of a host
computer through the electronic mail terminal.

CONSTITUTION: Working state information request mail is transmitted from
the mail terminal connected to an electronic mail system 2 constituted on a
first computer system 1 to the electronic mail system 2 so as to request
the report of the working states of a **second** computer system and a
related facility connected to the second computer system. This electronic
mail system 2 transmits the received working state report request mail to
the second computer system, and the working states of the **second**
computer system and the related facility connected to the **second**
computer system are **transmitted** through the **electronic mail** system
2 to the mail **terminal** as **state** information mail. This monitor system
uses such electronic mail.

ABSTRACT

PURPOSE: To ensure the unitary control of the terminal faults and to early restore these faults by transmitting and receiving the fault information through the remote terminal control systems of both terminal and host sides and updating periodically a data base file to display or print the fault information.

CONSTITUTION: A system controller 14 produces a fault confirming message through a remote terminal system 2 and sends the message to a remote terminal control system 7 in response to an inquiry given from an operation control terminal for the fault state. The system 7 retrieves a terminal fault control file 11 and produces a fault report message to send it to the system 2. The system 2 receives the fault report message and updates a fault state data base 9 with a terminal name used as a key. Then the system 2 shows a working state list and the fault state on the screen of a terminal display device 5 or prints them by a printer 13 in response to the request of the controller 14. In such a constitution, the unitary control is attained to the faults of the host side and the terminal faults can be early restored.

ABSTRACT

PURPOSE: To constitute a high-speed serial data transfer line by connecting plural microprocessor systems by a looped data transmission line when the microprocessor systems are used and transmit and receive data to one another.

CONSTITUTION: Microprocessor systems (A)101-(n)10n as (n) microprocessor systems are mutually connected in a loop shape by a data transmission line

CH and a receiving node select signal line L. IN regard to the microprocessor, only the desired receiving node receives the data by sending a receiving node0 select signal S specifying a receiving node as a previously set state through the receiving node select signal line L in the previously set state ; and other nodes are bypassed to eliminate the need for data reception, thereby speeding up the data transfer.

ABSTRACT

PURPOSE: To attain correct duplicate control by warranting the contact between pins and a mother board at the insertion/withdrawal in a live line state in the duplicate control circuit used for a circuit having a power application sequence.

CONSTITUTION: In the duplicate control circuits 1, 2 one of which acts like a master and the other of which acts like a slave through the setting of a mother board or the software control, when the length of pins of power terminals 11-14 is devised to be longer than the length of the other terminals in order to provide a power application sequence, the circuits 1, 2 are provided with malfunction prevention signal terminals 5, 6 whose length is the same as the length of other terminals 3, 4, 7-10 and with logic circuits 102, 202 confirming the output state of output terminals 9, 10 based on the output state of input terminals 7, 8 after the terminals 5, 6 are in contact with the mother board and earthing.

ABSTRACT

PURPOSE: To easily diagnose a program to be diagnosed without altering it while maintaining the state as it is by providing a pseudo input/output control part, which executes an operation equivalent with an input/output control part, between first and second computers.

CONSTITUTION: Between first and second computers 20 and 22, a pseudo input/output control part 25 is provided to execute the operation equivalent with the input/output control part. As a result, the program to be diagnosed executes an operation similar to be loaded to a real automatic transaction machine on the first computer 20, and the input/output signal is also exchanged completely without being different from the real automatic transaction machine. In such a state, when the second computer 22 generates the output signal in the completely same form as a real input/output device, the program to be diagnosed executes the operation corresponding to the output signal. Thus, when the input/output signal to be generated in various abnormal states is generated in the second computer 22, the operation of the program to be diagnosed to the various abnormal states can be continuously diagnosed at high speed.

ABSTRACT

PURPOSE: To prevent the runaway of a program by setting one specified terminal to a non-connecting state more quickly than other terminal and applying a reset to a program operation, when drawing out an extension memory cartridge.

CONSTITUTION: A home controller which can use an extension memory cartridge is constituted of a CPU 1, a CRT control circuit 2, a display memory 3, an I/O port 4, a main memory 5, a register 6, a card edge connector 7, a power-on reset signal generating circuit 14, etc. In this case, in connecting terminals of this cartridge, a CO terminal 21 is made shorter than **other terminal** and connected to a ground **terminal** 20. Also, a reset **signal generating** circuit 13 for detecting a connection release of this CO **terminal** 21, and **sending** out a reset **signal** is **provided**. In this state, in case of drawing out the cartridge, the CO terminal 21 becomes a connection release **state** more quickly than **other terminal**, and it is monitored and the reset signal is sent out, therefore, the whole device can be set to its initial state exactly.

ABSTRACT

PURPOSE: To shorten the picture drawing time as the whole, by setting a rotative movement command considering the circumferential length of a drum so that the drum is not rotated over the half of the circumferential length by the rotative movement command.

CONSTITUTION: A comparator 48 compares values of input terminals A and B with each other, and signal '1' is supplied to one input terminal of an AND circuit 58 if $A < B$ is true, and **signal** '0' is **supplied** to one input **terminal** of the circuit 58 is $A \geq B$ is true. Signal '1' is supplied from a line 54 to the other input **terminal** of the circuit 58 in the pen up state, and **signal** '0' is **supplied** to this **terminal** from the line 54 in the pen down **state**; and when two input **terminals** of the circuit 58 are '1' together, **signal** '1' is **supplied** to a control input **terminal** B of a data selector 60. If the sign of X movement data is positive, signal '0' is supplied from a line 56 to a control input terminal A of the selector 60; and if the sign of X movement data is negative, signal '1' is supplied from the line 56 to the terminal A of the selector 60.

Abstract (Basic): US 6446144 B1

NOVELTY - Multiple echo request **messages sent** simultaneously are **delivered** asynchronously to multiple **computers** in the **message** queuing system. Echo response **message generated** after receiving an echo request **message** , is **delivered** to the response queue. Indicia indicating the in-operation **state** of one of the **computers** is provided on a video display.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is included for

operation state monitoring system.

USE - Operation state monitoring method for computers in message queuing system containing large number of networked computers in distributed processing network.

ADVANTAGE - Provides an efficient and flexible way for the administrator to monitor the operating states of multiple computers in the message queuing system by performing asynchronous message delivery. Adjusts incoming data flow dynamically, enables to **send** echo request **messages** to multiple **remote** **computers** simultaneously, ensures that the packets transmitted by the sending node are received in order and only once by the receiving node, ensures that the message arrival rate does not exceed the capability to handle the message packets, reduces data traffic for session connection and coordinates message transmissions in both directions to avoid transmission collisions.

DESCRIPTION OF DRAWING(S) - The figure shows the schematic diagram of the message queuing system.

US 6430700	B1	19	G06F-011/00		Cont of application US 9867482
					Cont of patent US 6269452

Abstract (Basic): US 6430700 B1

NOVELTY - The method involves **sending** a first **message** from the first **node** (202a) to a **second node** (202b) after detecting a situation by the first node. A fault recovery procedure is initiated in response to the first **message**. A second **message** is then **sent** from a new **node** to the **second node**. An idle **state** is entered if the determined source of the **second** message is a **node** other than the first **node**.

DETAILED DESCRIPTION - The first node is adjacent the second node

prior to the addition of the new node, but is no longer adjacent to the second node subsequent to the addition of the new node. The source of the second message is determined to be a node other than the first node after the reception of the second message at the second node from the new node. INDEPENDENT CLAIMS are included for the following:

(a) the fault recovery system for ring computer network;
(b) and the computer program product for fault recovery in a ring computer.

USE - Adding a new node to a ring computer network.

ADVANTAGE - Provides protection protocol for fault recovery for a two line bidirectional ring network. Simplifies coordination required by the nodes in a ring network, in which nodes do need to maintain a topology map of the ring, identifying and locating each node in the ring, for effective protection. Provides multiple levels of protection priority.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of a ring network utilizing a protection protocol.

Abstract (Basic): US 20010038611 A1

NOVELTY - An upstream of laser signal generated is transmitted to a central office (CO) (110) and downstream of optical signals are

converted into electrical signal. A portion of downstream signals are mixed at a **node** (140) remote from CO to **generate** upstream frequency shifted data **signals** which are optically **transmitted** to CO, where **state** of remote **node** is determined by monitoring **generated** laser **signal** and frequency shifted data signals.

USE - Used in broadband communication network for monitoring state of communication system remotely located from central office in communication technology.

ADVANTAGE - Integrity of transmission paths in a communication network is improved and remote active components are successfully monitored.

DESCRIPTION OF DRAWING(S) - The figure illustrates a block diagram of bi-directional communication system.

NOVELTY - The request from first node is sent to **second** node over a second route between **nodes** for **status** information indicating **messages** previously **transmitted** over the first route, based on which a **status** information from the second **node** is **sent** to the first **node** . **Message transmission** between the **nodes** over the first route is resumed according to transmitted status information.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is included for virtual route synchronization apparatus.

USE - In data communication network used to transmit information between geographically dispersed computers and between user devices such as computer terminals or workstations and host computer applications.

ADVANTAGE - Enables quick resynchronization of message traffic with low system processing overhead.

DESCRIPTION OF DRAWING(S) - The figure represents flowchart describing the virtual route resynchronization process.

JP 2002500785 W 50 G06F-015/177 Based on patent WO 9826553

Abstract (Basic): WO 9826553 A

The program includes a computer usable medium with computer readable code embodied for causing re-assignment of computer services from one host to any of a number of other hosts within a service group. A first computer readable program code is configured to cause a computer to transmit a message setting forth the state of the computer. A second computer readable program code is configured to cause a computer to receive a message from other computer. A third computer readable program code is configured to respond to messages to acquire or release computer services. The messages to acquire or release computer services are the result of the failure of another host within the service group. The messages to acquire or release computer services are the result of load balancing within the service group. A service group comprising a number of host computers is established, which can provide a computing service.

ADVANTAGE - Can be added or removed without reconfiguring remainder of system forming network.

Patent Details:

Patent No Kind Lan Pg Main IPC Filing Notes
US 5717862 A 7 G06F-013/00

Abstract (Basic): US 5717862 A

A number of copies of a message are transmitted in the direction of the **destination** node via a number of paths to a number of child **nodes**, which in turn **transmit** the **message** to further child **nodes**. If a node is in a busy **state** it transmits to its parent **node** a **'Link cancel'** status message indicating that the link is to be severed. The parent **node** then **transmits** the **status message** to its own parent **node**.

When the **destination node** receives the **message** it **transmits** a **'Lock-up'** **message** to the parent **node** from which it received the **message**. The parent **node** **transmits** the **'Lock-up'** **message** further when it has received status messages from all of its child **nodes**, ensuring that the source node knows that when it receives the **'Lock-up'** message all the child nodes have dumped their duplicate copies of the original message.

ADVANTAGE - Unsuccessfully transmitted message copies are quickly eliminated from communication pathways. Data transmissions are controlled to accommodate clock variations in different nodes.

Patent Details:

Patent No Kind Lan Pg Main IPC Filing Notes
JP 9319720 A 11 G06F-015/16

Abstract (Basic): JP 9319720 A

The system includes three system process management units for program control. A self-system process management unit controls the execution of a program in a self-system computer connected to other system computers via a network. The self-system process management unit demands the start, the termination, and synchronisation of the program

and performs the transmission of a signal. Commands corresponding to the execution start and synchronisation of the program in **other system computers** are published together with the **signal transmission** request by **other system computers**.

A self-system process monitoring circuit monitors the state of the program operating in other system computers. The published requests of other system computers are received by the self-system process management unit. The processing result of the self-system process management unit in the self-system computer is reported to other system process monitoring circuits.

ADVANTAGE - Confirms request of **transmitting** data and program **signal** by published **computer**. Load and **state** of **other system computers** can be recognised by self-system computer. Restrains generation of fault.

JP 3326672	B2		11	H04L-012/56	Previous Publ. patent JP 9091218

Abstract (Basic): JP 9091218 A

The method involves using a **communication** network through which a **message** is **transmitted** to a number of **clients** from a **server**.

When all the **clients** have not received the **transmitted message**, the incomplete reception is notified to the **server**. The **server** retransmits the message to the client by managing the message receiving **state** of the **clients**.

ADVANTAGE - Prevents increase in waste communication. Improves rate of completion of message reception of client.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 8249258	A		5 G06F-013/00	

Abstract (Basic): JP 8249258 A

The controller includes first and second connectors (35,36)
respectively linked to the first and **second computers** . A
communication signal line (31) is connected to a transceiver of each
computer . A **communication signal** feedback line (32) is **formed**
at a communication path to pass a standard voltage of the communication
line. A pair of ground terminals are provided to pass the standard
voltage of each computer. Supervisory-signal terminals are respectively
connected to each computer through a resistor. A first monitoring
signal line (37) connects one supervisory-signal terminal and the other
ground terminal. A second monitoring signal line (38) links the other
supervisory terminal and one ground terminal.

The voltage of the each supervisory terminal is input by a
connection state distinction circuit (12). When there is no voltage at
the supervisory-signal **terminal** , the connection **state** of the
computers is decided normal. When there is voltage at the supervisory-
signal terminal and the **communication** path is detached, it will be
distinguished by the connection state distinction circuit.

ADVANTAGE - Distinguishes connection state of computers easily.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 7311732	A		19 G06F-013/36	

Abstract (Basic): JP 7311732 A

The scanner reads an image data from an original image source (72) with the use of a photoelectric conversion unit (74). The scanner has a parallel interface (82) which is connected to a first computer (40), and an SCSI interface (84) which is connected to a second computer (42).

The bidirectional interfaces transmits the read image data from the first computer to the second computer or vice versa. If one of the computer has accessed the scanner, the other computer will receive a busy state signal from the scanner.

ADVANTAGE - Promotes efficient and flexible image scanning due to enabling of bidirectional image data transfer between several computers of different architecture. Enables transmission of busy state signals to other computers when computer has already accessed scanner, thus ensuring normal operation during simultaneous access. Effectively prevents computer operation hanging due to interface function, thus increasing efficiency of information processing.

Abstract (Basic): EP 661644 A

The method of controlling **transmission** involves **transmitting** a ready message from one **destination node** to a source node indicating that it can receive data. A data **message** is **sent** to the **destination node** from the source in response. A conditional disconnect **message** is **transmitted** from the **destination node** to the source after a **given** slice of the data **message** has been received.

When the source node receives the conditional disconnect message, it continues transmission until a given condition occurs. This condition may be that the **message** has been completely **transmitted**, that a disconnect **message** is received from the **destination node**, or that new ready message is received.

USE/ADVANTAGE - For data processing system. Allows part of data to be transmitted even if interruption occurs by use of conditional disconnect message.

US 5404565	A		13	G06F-013/00		Cont of application	US 91741546

Abstract (Basic): US 5404565 A

The network includes a source node in which a message is originated, a **destination node** : where inter- **node transmission** of the **message** is terminated and one or more intermediate node(s) through which the message travels before arriving at the **destination node** . The intermediate **nodes** are connected between the source and destination nodes.

The network includes a message progress reporting system through which a received **status** word enables a source **node** to determine a **message** 's **transmission** progress through the multiple **node** network. A node contain a transmitter coupled via communication links to a number of child **nodes** , for **transmitting** a **message** to at least one the child node.

USE/ADVANTAGE - For reporting max message progress in computer network. Provides each message transfer completion or error reports.

Abstract (Basic): WO 9217961 A

The system (10) has a network (12) with N nodes (14), each able to execute a diagnosis algorithm. N is greater than or equal to 3 and each of the nodes is in communication with at least one other node by way of the network. Each node also has a way of testing whether a node is in a desired or undesired state, and which node to test based on the circumstances.

ADVANTAGE - Testing structure of algorithm is determined by fault situation in network, thus preventing faulty nodes from passing on erroneous results about rest of network.

Abstract (Basic): CA 1307854 C

The local area print server is for connecting a printer to a data processing system via a local area network. The data processing system

includes host nodes and a resource **server** node. The local area print server has network facility device connected to the local area network for **transmitting** resource request **messages** to the resource **server** **node** and receiving printer resource data in response. A resource data storage device is connected to the network facility for storing printer resource data received from the resource server **node**. A **status** collector device is connected to the printer for receiving printer status messages. The printer status messages includes printer resource fault messages.

A resource manager device is connected to the network facility device, the resource data storage device, and the status collector device, for determining, upon receipt of a printer resource fault message by the status collector device. If required, resource data is stored in the resource data storage device and if so, for causing the required resource data to be transmitted to the printer, and if not, for forwarding a resource request message to the network facility device.

USE/ADVANTAGE - For producing printed records of data interchanged and generated by other elements of computer system. Higher speed processing of printing requests. smaller memory requirements of printer.

JP 5063758 A H04L-029/10
EP 504087 A3 H04L-029/06

Abstract (Basic): EP 504087 A

In the method a message from upper layer of a node is sent to a lower layer of the same node and an initiation flag in messages is set to ON. In response to first message a second message is transmitted including a flag to a lower layer of second node, which is a command or a response in accordance with send process state of lower layer of first node. In upper layer of a node receipt is detected of a fourth messages from first node lower layer corresponding to third message from second node. If the initiating flag is ON, fourth messages determine primary or **secondary status** of a **node** according to predetermined criterion. If the **node** is primary, first **message** is **sent** , until flag is OFF, and all subsequent flags are set to ON relating to the first message. If the first node is secondary, the fourth message is discarded and the flag is set to OFF in subsequent messages.

ADVANTAGE - Protocol going on at higher layers of two nodes resolve in synchronisation with protocol going on at lower layers.

Abstract (Basic): US 6347339 B1

NOVELTY - An invalid login command (206) containing invalid login information, is generated from an **active node** to **another node** and **communicating network messages** for a predetermined period. The response of the **other node** of refusal to execute the login command, is checked for identifying the **node as active**.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (a) Network node;
- (b) Computer readable medium storing sequence of instructions for identifying **active nodes** in **computer network**;
- (c) **Active node** detection apparatus

USE - In computer networks using Telnet protocol for identifying **active nodes**.

ADVANTAGE - Enables easy identification of **active nodes** even by using invalid user identifier and user password parameters to a node.

DESCRIPTION OF DRAWING(S) - The figure shows the flowchart explaining the **active node** identifying method in **computer network**.

Invalid login command (206)

Abstract (Basic): US 6337852 B1

NOVELTY - The data portion of a **message** and related control information are **transmitted** from a source **node** to a **destination node** . When there is no space in buffer to retain the data portion of the message, the data portion is discarded by the destination **node** . When space is **available** in the buffer, a retransmission of the data portion from the source node is initiated using the related control information.

USE - For controlling **transmission** of **messages** from the source **node** to the **destination node** in multiprocessor data processing system.

ADVANTAGE - Prevents the performance degradation associated with packet transmission after time-outs. Provides efficient transmission and flow control of messages.

DESCRIPTION OF DRAWING(S) - The figure shows a protocol diagram of flow control technique in which data portions of messages are discarded by the destination node and later retransmitted from source node in response to pull requests from destination node.

Abstract (Basic): US 6247055 B1

NOVELTY - The client (131) receives an unique identifier assigned to particular **server** , during initial connection. The **client sends** a **message** to any active **server** in the **computer** network, to receive different network address associated with received identifier. The **client sends** another **message** to the different network address, to re-establish connection with the particular **server** .

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (a) Method for re-establishing connection to failed database manufacturing system (DBMS) server;
- (b) Method for establishing connection between client server;
- (c) System for re-establishing connection to failed DBMS server;
- (d) System for establishing connection between client and server;
- (e) Computer program product

USE - For enabling a client system networked in sysplex environment through TCP/IP network to locate specific server. Also for use with multiprocessor network, file server, print server, file transfer programs (FTP), etc.

ADVANTAGE - Preserves ability of client to access the sysplex seamlessly. Enhances work load balancing and data availability. Allows two-phase commit protocol to work properly even when DBMS server's network attributes are impacted.

DESCRIPTION OF DRAWING(S) - The figure shows the explanatory drawing of sysplex environment.

US 6205498	B1		13 G06F-013/14	

Abstract (Basic): US 6205498 B1

NOVELTY - An acknowledgement time-out period is returned to a node from another node, based on which data packets are transmitted. A session acknowledgement with window size field specifying a new window size for message transfers message to dynamically adjust maximum number of message packets based on the resources **available** on the **node**, is sent to the previous node.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(a) System for managing message transfer session;

(b) Message transfer session managing program

USE - For managing message transfer session between nodes in computer.

ADVANTAGE - A multi-ping mechanism implemented with asynchronous message delivery allows an administrator to check the operating system of multiple computers in the message queuing system. A ping-originator application **sends** echo request **messages** to **remote computers** simultaneously.

DESCRIPTION OF DRAWING(S) - The figure shows the schematic diagram of nodes in a message route communicating with each other during message transfer session by passing packets.

Abstract (Basic): WO 200003344 A1

NOVELTY - A local area network (50) with a file server (45) is connected to a pharmacy computer (60), a nursing station (70) and a bedside CPUs (80). The file server (45) stores programs and data which are input and collected by the various computers in the network.

DETAILED DESCRIPTION - The system has a medical administration management module integrating medical order information, infusion pump monitoring, and bar code technology to support the real time verification and charting of medications administered to a patient. The module gathers information from various nursing and bedside CPUs and creates and maintains an online, real time, patient specific medication administration record. When a physician attends a patient and specifies the desired therapeutic treatment, the prescription is entered into the pharmacy information system and then entered into the care management system. An infusion pump (92) delivers medication to the patient in a predetermined, controlled manner. The sensors and **send signals** to the **computer** for storage **available** for remote access by the file **server** (45). The care management system controls alarms or alerts generated by a module of the system.

USE - Used for automated patient care management.

ADVANTAGE - Monitors, controls and tracks the administration of care in health care institution. Enables the administration to project supply usage and purchase supplies in quantities without incurring inventory carrying costs.

DESCRIPTION OF DRAWING(S) - The drawing is a graphic representation of the care management system illustrating details of the hardware elements and local area network.

Abstract (Basic): US 5878223 A

NOVELTY - A server (130) sends predicted page of information by determining a preference factor for the page based on the pages requested by a client (12). The predicted pages are stored in a cache memory (80) in the client.

DETAILED DESCRIPTION - The predicted pages are sent to the **client** only when a permission **signal** is **sent** by the **client** to the **server**. The permission signal indicates that sufficient memory is **available** in the **client** to store the predicted page and the requested page is requested in a specified period of time, and if there is a preference factor related to the predicted page. The sending of predicted page terminates when another request for a requested page is received. AN INDEPENDENT CLAIM is also included for a method for web page transmission.

USE - In server computer for internet.

ADVANTAGE - The bandwidth and apparent speed of the network connection is increased by sending pages of information from server to the requesting computer effectively.

DESCRIPTION OF DRAWING(S) - The figure represents pictorial representation of computer system and block diagram of computer network comprising server and requesting computer connected via interim computer.

Client (12)
Cache memory (80)
Server (130)

------------	---	--	--	-------------	---------------------------

Abstract (Basic): EP 295380 A

When any link in the network is activated, a first exchange of signals is initiated automatically between nodes (as EN, NN) attached to the link. This provides each attached node with information about the availability of the node at the other end of the link for participating in a predetermined type of communication session. In response to the information it is determined at each attached **node** if both **nodes** are **available** to participate in the predetermined session type.

If both are available an automatic second exchange of signals is initiated between the nodes for setting up a session. Following establishment of a session, a third exchange of signals is initiated automatically to provide signals which give the nodes the necessary information for making effective use of the session. The session is then made available to transaction programs for exchanging additional network state data as necessary.

Abstract (Basic): WO 8808579 A

The bus request is generated at times when a message is to be transferred from a node onto the bus (25). A request is output on a respective bus request line to the arbiter (28) using a respective pair of dedicated lines. An extend request generator (111) produces an extend request for each node which requires more than one bus cycle for transferring a message.

Extend cycle circuit (122) in the clock decoder (63) acts for activating an extend bus cycle during the initial access cycle when the node becomes a transmitter and for maintaining the extend bus cycle signal activated during successive bus cycles while the extend request for the node is present. An enabling circuit (124) produces a system has drive enable signal in the node when no extend has cycle signal from other nodes is active and whilst the extend bus cycle signal for the respective node is active.

Abstract (Basic): EP 248508 A

Each computer, when it does not have control of the bus, monitors for messages destroyed for it. If it does not detect any messages within a given time interval it enters a contention mode. In this mode it respectfully broadcasts a contention message over the bus at a given repetition rate until either it received a response to the message, in which case it assures control of the bus, or it receives a contention message from another computer, in which case it sends a response to that other computer allowing it to assume control of the bus.

Each computer has a different repetition rate at which it sends messages in the contention mode such that, whatever the initial phasing of the contention messages from the computers is the contention mode, one message from one of the computers will always be transmitted without collisions within a given no. of transmissions.

Abstract (Basic): US 4630196 A

The system comprises means for creating a message file in response to instructions from an originating **computer** process, and means for delivering a message to a destination computer process. Information in a message file is transferred to the delivering means. The delivery includes a circuit creating the **destination computer** process from a destination program. The **create** circuit is notified that a **message** is available for **delivery** to the **destination computer** process.

A circuit is responsive to a release request from the **destination computer** process to **generate** a confirmation **message** to be **transferred** and **delivered** to a **computer** process specified by the originating computer process.

ADVANTAGE - Increased delivery speed.

ABSTRACT

PROBLEM TO BE SOLVED: To provide a server and a portable terminal for electronic mail to improve convenience of an electronic mail function without impairing portability of the portable terminal.

SOLUTION: The **electronic mail** transmitted from **computers** 4a, 4b,... through a computer communication network 2 is distributed to the portable **terminals** 6a, 6b, ' **connected** with a telephone line 5 by the server 1 for electronic mail. The electronic mail is stored in an electronic mail storage means 1a included in the **server** 1 for **electronic mail**. In-coming mail information is **given** to the portable **terminals** 6a, 6b,... only when the electronic mails transmitted to users of the portable terminals 6a, 6b,... are the electronic mail from transmitters who are registered in a transmitter's directory stored in a transmitter's directory storage means 1b with respect to an in-coming mail informing means 1c. Therefore, only the in-coming electronic mails from important transmitters are informed to the portable terminals 6a, 6b,... by the in-coming mail informing means 1c.

ABSTRACT

PURPOSE: To distinguish a state where a communication route is detached

from a state where the power supply to a computer is cut.

CONSTITUTION: This controller is provided with the communication route 30 connected through a first connector 35 to one **computer A**, connected through a second connector 36 to the other **computer B** and provided with a communication **signal** line 31 connected to the **transmission** /reception circuits 11 and 21 of the respective **computers** and a **communication signal** feedback line 32 for **supplying** the reference potential of the **communication signal** line 31, monitoring **signal terminals** 15 and 25 respectively **provided** in the **computers** and **connected** through a resistor R to the power supply voltage Vcc of the present computer and grounded terminals 16 and 26 for supplying the reference potential of the present computer. Then, the communication route 30 is provided with monitoring signal lines 37 and 38 for which the monitoring signal terminal of one and the grounded terminal of the other are mutually cross-connected and the respective computers are provided with connection state discrimination circuits 12 and 22 for inputting the potential of the monitoring signal terminal of the present computer. It is judged as normal when the potential of the monitoring signal terminal is '0', and it is judged that the communication route 30 is cut off when it is '1'.

ABSTRACT

PURPOSE: To cope with an infringement of security that a wrong intruder from one system wrongfully accesses another system in open systems.

CONSTITUTION: At least one or more security audit **server** (SO) is provided in open distributed network systems (SS1, SS2, SS3...) and this SO always extracts and analyzes security **messages** (M1, etc.) which are **transmitted** from **work stations** (WS11, etc.) **connected** to networks and are related to the infringement of security and collects and accumulates the results. In the case of the message which may have an influence upon systems, a security report related to this message is generated. All security reports are synthetically analyzed to diagnose the weak points of systems, and the proper change of the security policy is requested to actual systems.

JOURNAL: Section: P, Section No. 1527, Vol. 17, No. 215, Pg. 65, April
 27, 1993 (19930427)

ABSTRACT

PURPOSE: To set the same time to computers on a network without mutual adjustment.

CONSTITUTION: In the network time synchronizing system where times of plural **computers** connected through a local area network are synchronized, the **computer** having a time **generating** device **transmits** a time **message** at intervals of a certain time by radio, and the **other computers** receive this time message to extract time data and check it; and if it is correct, they set the present time based on this time data. If it is not correct, they transmit a data retransmission request to the computer having the time generating device. Thus, the time lag from time acquisition to time setting is eliminated to suppress the increase of load of the network due to complicated calculation processing.

Abstract (Basic): US 20010001151 A1

NOVELTY - Interconnect (serial bus) comprises two coupled nodes, with a third **node** connected after the interconnect is initially configured. The first node initiates a new connect handshake with the third by **transmitting** a **signal** to it and **signals** that the third **node** has been added to the interconnect if it responds to the first **signal** by **transmitting** a **second signal**. The first **node** causes the interconnect to be reconfigured if the third **node** **transmits** a third **signal** in response to receiving the first signal.

DETAILED DESCRIPTION - The bus is initially configured for the first, second and a fourth node, the latter assigning an address to the third node to signal that the third node has been added in response to the first node signaling. There are INDEPENDENT CLAIMS for (1) an electronic system, (2) a serial bus, (3) a method of adding a new node to a previously configured serial bus, (4) a node for use in an electronic system interconnect, and (5) a method of building a topology map of an interconnect.

USE - Interconnect (serial bus) is for information sharing in a computer system.

ADVANTAGE - Interconnect enables nodes to be connected and disconnected from the serial bus to reduce interruptions to serial bus traffic.

DESCRIPTION OF DRAWING(S) - The figure shows a serial bus.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 11249996	A		5 G06F-013/00	

Abstract (Basic): JP 11249996 A

NOVELTY - Terminal equipments (102-104) are connected in a system via local area network (LAN) (101). External storage devices (105-107), connected to terminal equipments, store only notice data index simultaneously. Each terminal equipment indicates the modification of the notice data content by **sending** a change notice **signal** to **other terminal** equipment showing the modified notice data.

USE - None given.

ADVANTAGE - Reduces redundant resources since only index data are exchangeable within each terminal and unnecessary data are not passed. Prevents one terminal from overload concentration since dispersion and modification of data are performed. DESCRIPTION OF DRAWING(S) - The figure shows the diagram of the bulletin board system. (102-104) Terminal equipments; (105-107) External storage devices; (LAN) (101).

Abstract (Basic): WO 9859299 A

The communications system has a number of clients (10,24) that can connect to a network, e.g. the Internet. As the clients use a telephone connection (18,26) to link to the network, they cannot concurrently handle telephone calls. The clients log on to a service provider site (14). The client computers also have software that automatically logs on to another server (16). This server maintains a directory of possible clients.

This **server** also holds a directory of **clients** currently **connected**. Periodic messages detect whether **clients** are still **connected** to enable database maintenance. **Clients** can **send messages** to other users currently on-line.

ADVANTAGE - Allows on-line users to receive messages from others despite telephone line being in use.

Abstract (Basic): EP 872984 A

The method transmits data (135) stored on a first **computer** system connected to the global computer network (130) to a **second computer** system **connected** to the global network. A receipt acknowledgement **signal** is **sent** from the **second computer** system to the first on receiving the data on the **second computer** system.

Acknowledgement signals received by the first computer system are monitored to determine whether the data has been received by the second computer system. The data is automatically transmitted via facsimile upon determining that the data has not been received by the second computer system together with an automatic paging signal.

USE - For performing EDI (electronic data exchange interface) transactions over global computer network.

ADVANTAGE - Allows for secure data transfer operations to be performed on line in real time.

JP 10224396 A 20 H04L-012/54

Abstract (Basic): JP 10224396 A

The system includes several **computers** which are **connected** via a network. A transmission side **computer** (2) consists of a **message transmitter** which **transmits** the **message** produced by a **message**

production unit to the network. The modification factor related to the modification of the produced message is stored and managed by a first management unit (21). The conditions on which the produced message should be modified according to the modification factor, are set up by a condition setting unit (23). A **server computer** (1) stored the **message transmitted** to the network in a first memory. The second management unit (11) provided in the sever computer stores and manages the modification factor.

When the message of a self address is stored in the first memory, then a message receives (30) of a receiving side computer (3) receives the message from the server computer via the network and stores the message in a second memory. A third management unit (33) in the receiving side computer stores and manages the modification factor. The contents or the display of the message currently stored to the second memory, are modified according to the modification factor stored in the third management unit.

ADVANTAGE - Modifies message contents, according to modification factor. Improves communication efficiency

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
US 5761425	A	11	G06F-013/14	

Abstract (Basic): US 5761425 A

The system includes host computer (16,22) and terminals connected in WAN and several **work stations** (10,20) **connected** in LAN. A first connection is performed between the WAN and **server**. A first, **second** and third **computer** programs are provided for **server**, host computers and **work stations** respectively. These **computer** programs **send** and receive **messages** using a matching application level protocol thereby, facilitates data transfer. An automatic connection unit connects WAN side terminals to LAN side work stations. An authenticating unit authenticate users who are seeking access to LAN side work station.

A specific unit facilitates user to view and manage data on the LAN side work stations. A second connection unit facilitates user to connect other work stations to the LAN using the matching application level protocol, a communication unit transfers data between host computer and network work stations.

ADVANTAGE - Increases throughput. Facilitates user to provide WAN to LAN and LAN to WAN connection. Reduces data communication time, remarkably. Possesses authentication capability to verify user's privilege before permitting access to LAN.

Abstract (Basic): JP 10107850 A

The system makes use of several computers (20) which are connected through a communication circuit (12). A transmitting request signal is transmitted from one computer to other computer through a communication circuit.

The computer which receives the transmitting request signal, transmits request information corresponding to the received signal to the computer which sends the request by using an information transmitting unit. Then, the received information is regenerated at the computer.

ADVANTAGE - Improves activity.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 7282011	A	15	G06F-015/16	

Abstract (Basic): JP 7282011 A

The distributed transaction processing system (10) has a number of computers which are connected to the communication network. The application program counter is inserted in a transaction branch (16) by the user, and the transaction is parallel processed by the computer. The stored commitment controlled message (3482) is transmitted by the computer to the concerned node (32) for every print node.

When a constant amount of message is stored in a transmitting buffer (348), a transmitting management device (344) makes the package transmission of a number of messages as one message to the target node. A management device (342) receives the package transmission of messages and decomposes into a number of original control message.

ADVANTAGE - Makes transmitting and receiving messages into number of blocks. Improves processing. Carries out transmission and reception collectively.

Patent Details:

Patent No	Kind	Lan Pg	Main IPC	Filing Notes
JP 7093227	A		7 G06F-013/00	

Abstract (Basic): JP 7093227 A

The method involves specifying a **message transmission** category to particular **computers** (1) **connected** to the network. The **terminal** of the calling party (1a) **sends** a **transmission** demand having a **message** ID to the receiving parties (1b, 1c, 1d) which are assigned to the same message transmission category.

The receiving parties comply with the demand by sending messages in demand driven format preceded by their message IDs to the calling party. The calling party then selects which message will be read first.

ADVANTAGE - Saves memory space. Avoids delays in delivery of messages.

DE 3586431 G G06F-015/16 Based on patent EP 374132

Abstract (Basic): EP 374132 A

Each node (34) sends periodically an advertising message to all device servers (24) to identify the respective node and the services provided by the service providers (14) connected to that node, together with a rating for the service. When a user (12) needs a service provided by a service provider (14) identified in a service directing in the respective server, the server begins to set up a virtual circuit between itself and the node which provides the service being the most desirable service rating.

A virtual state machine is set up for data communications between the **server** and the **node** over a communications link. Each **node** receives **messages** from the link and **sends messages** each including a data field and a response requested flag field having predetermined values which are established in response to the data field being empty.

ADVANTAGE - Message throughput between users and providers of services is enhanced and units have equal access rights to communications links of sending messages. (23pp Dwg.No.1/8
